FINCH

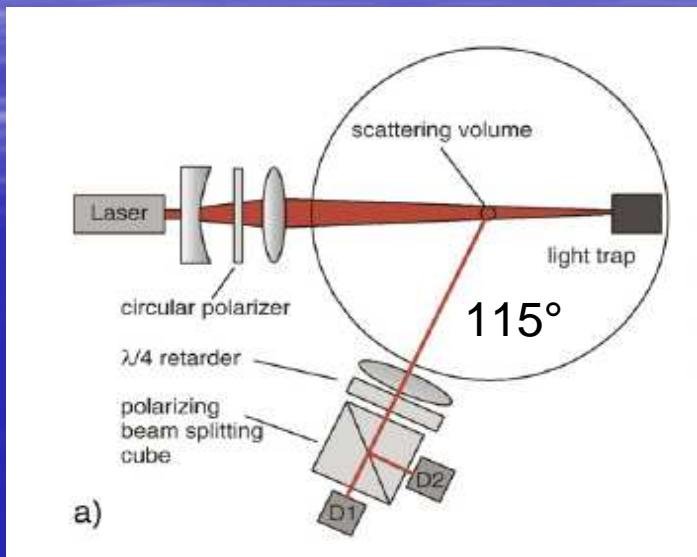

Bundke et al., Atmospheric Research, 2008

- Mixing of 3 gas flows
- Total flow 40-80 l/min
- Aerosol flow 1-10 l/min

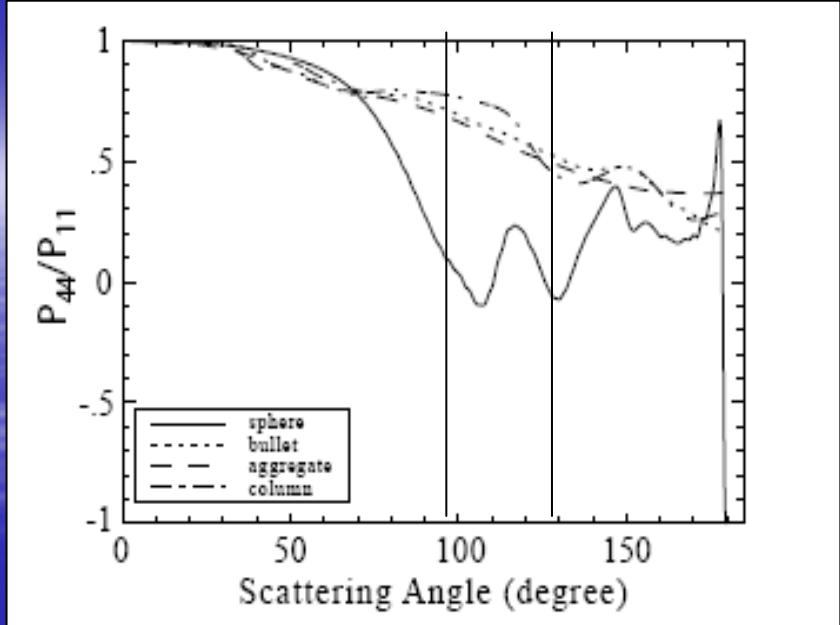

Activation of IN and CCN at pre selected temperature and super-saturation

- cooled processing chamber of 1,3m
- virtual impactor
- distinguish between ice crystals and super cooled water droplets

Optical detector (new development)

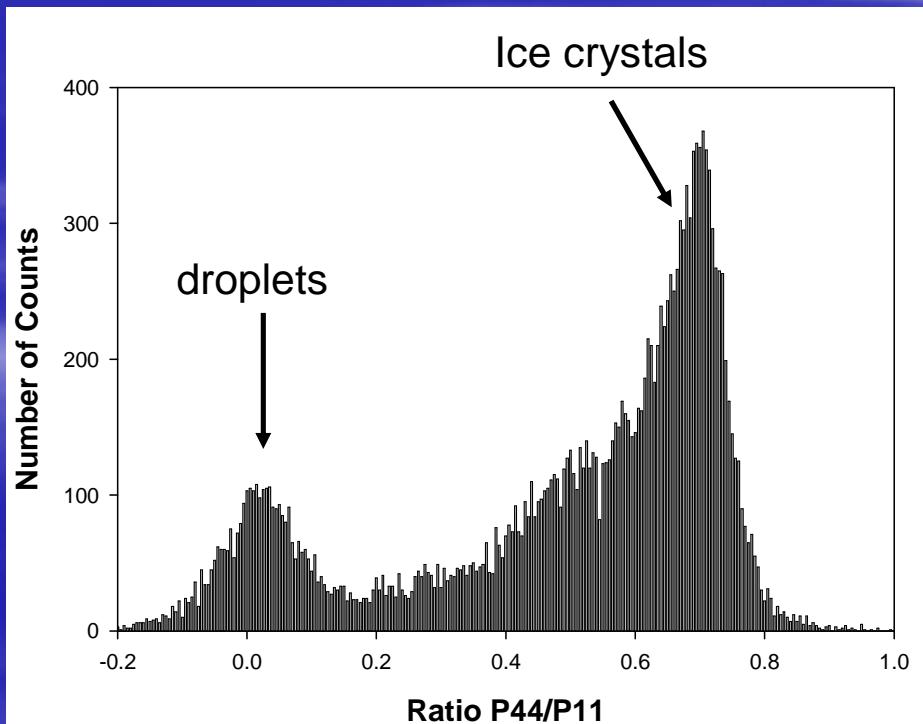

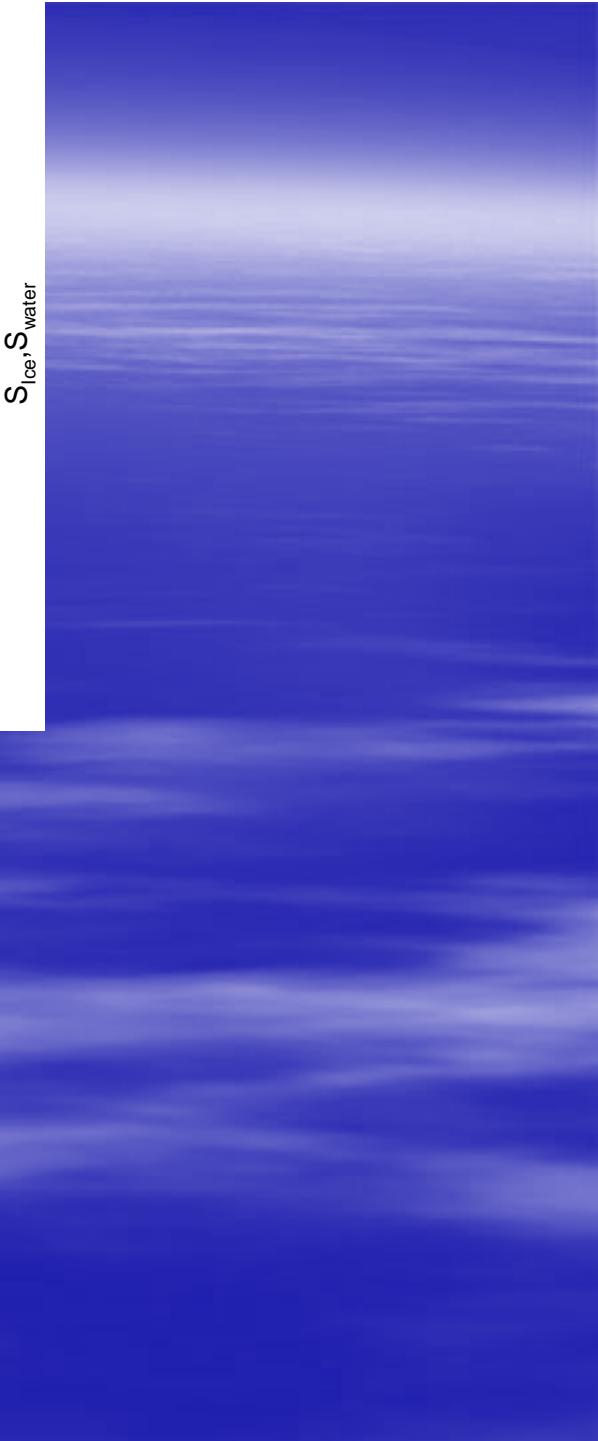

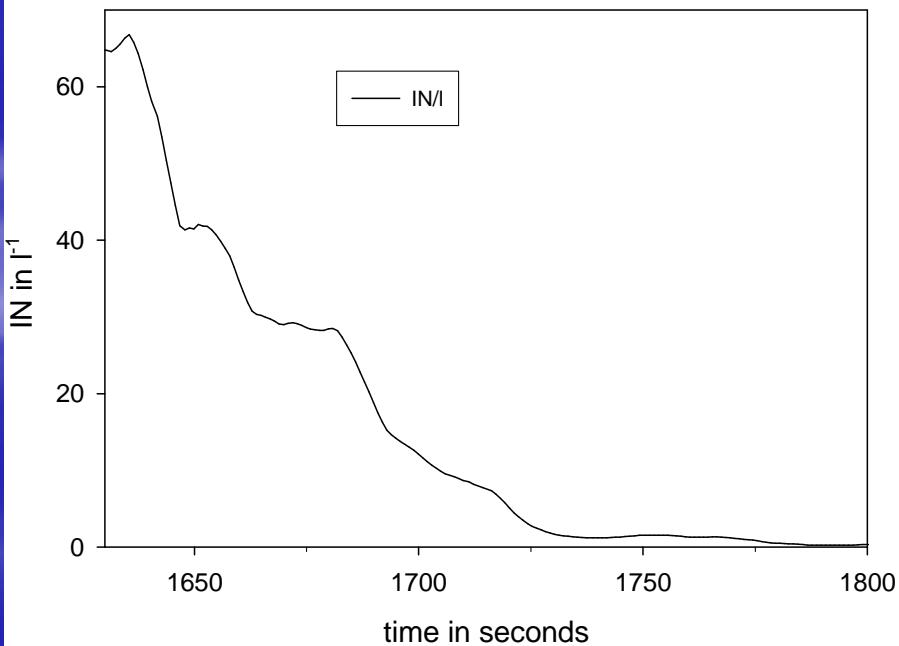

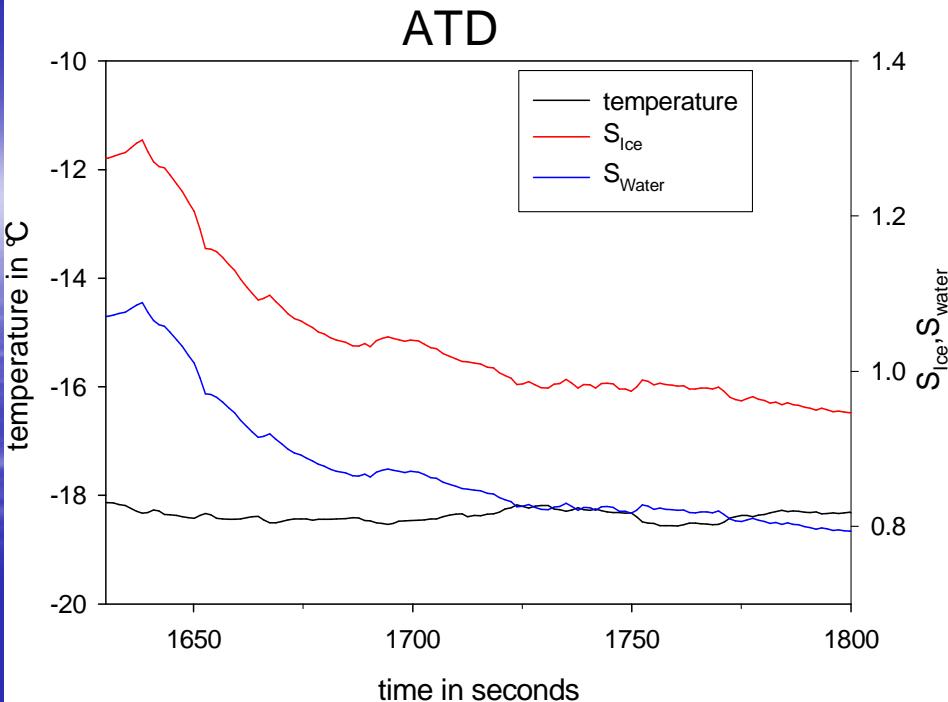

- circular polarized laser beam
 - backscattered light is detected and analyzed for the circular polarization under an angle of 115°
 - separate detectors measure the two perpendicular linear polarized beams
- calculation of the ratio of P44 and P11 of the scattering matrix

(Y.-X. Hu et al. / Journal of Quantitative Spectroscopy & Radiative Transfer 79–80 (2003) 757–764)

- Different ratio P_{44}/P_{11} for supercooled droplets and ice crystals

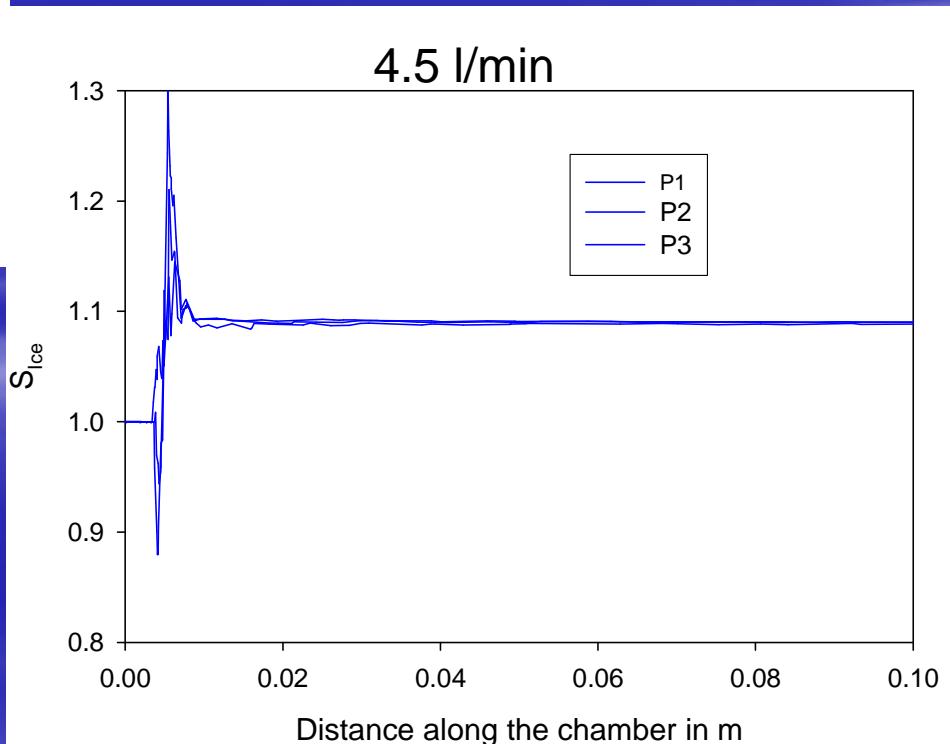

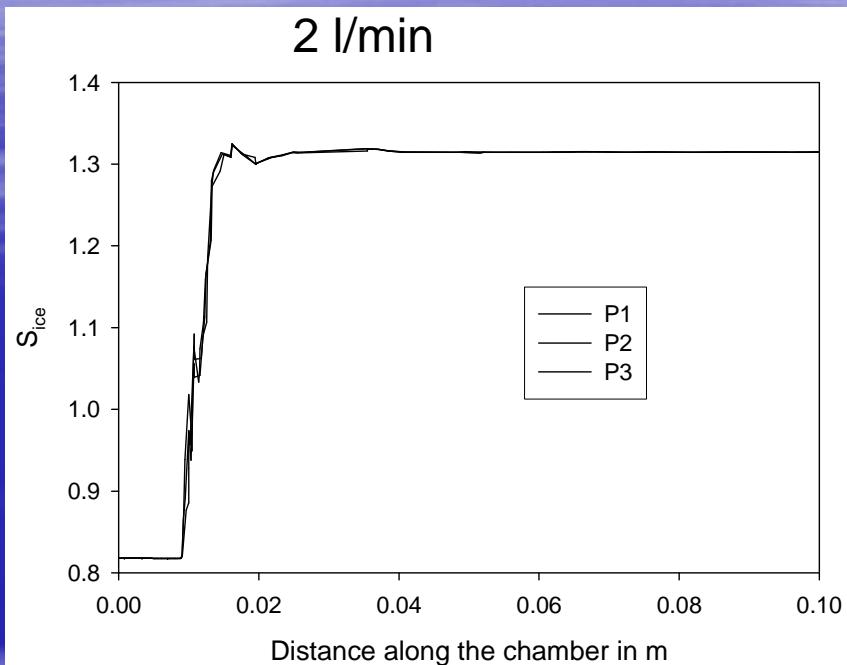

The International Workshop on Comparing Ice Nucleation Measuring Systems (ICIS 2007)

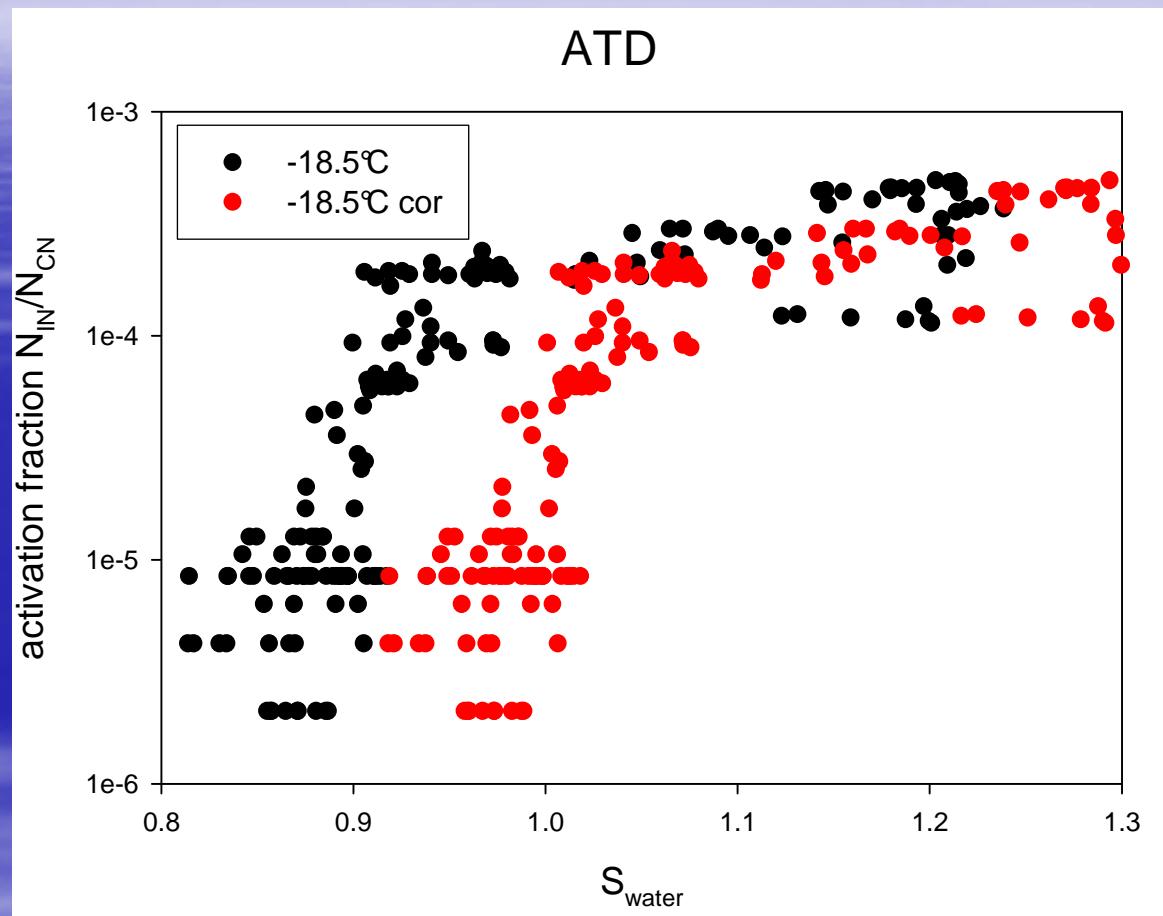

Problems:

- No supersaturation at the beginning (NAUA measurements)
 - Dry air from the NAUA
 - Humidified the sample flow
 - freezing of the inlet
(only short measurement periods possible)
 - Leak at high pressure side of the pump → 4.5 instead of 2 l/min sample flow
- activation at lower supersaturation, lower IN number concentration

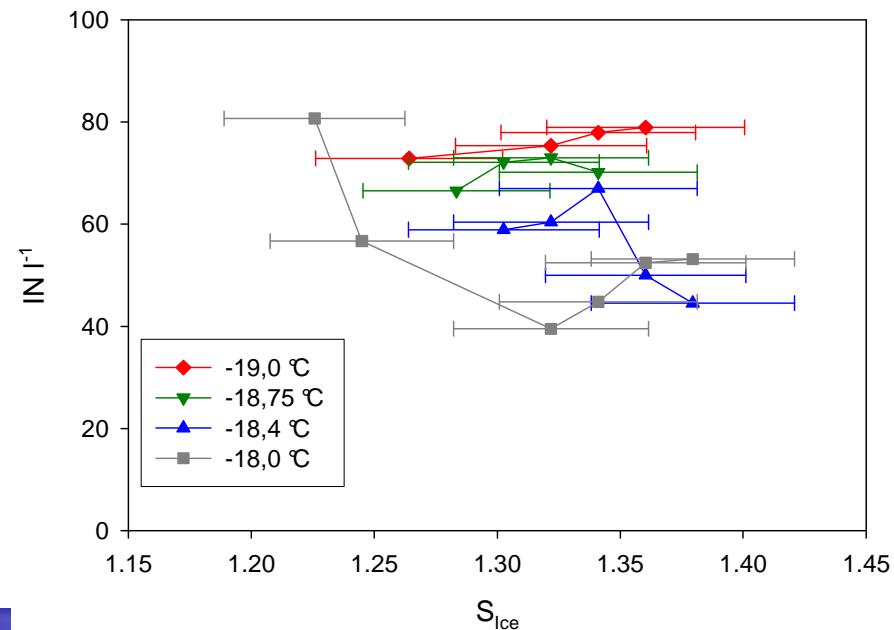

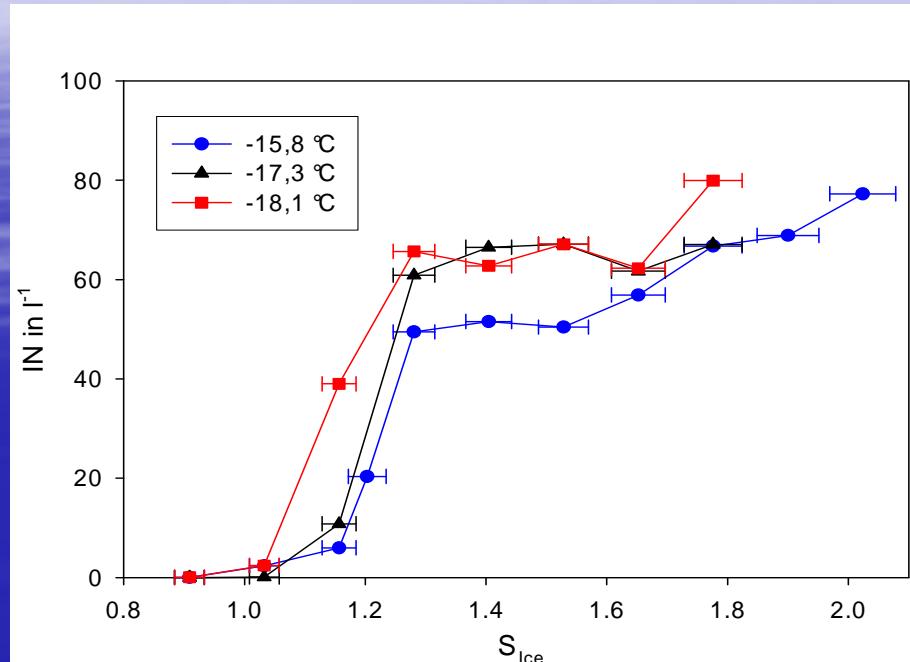

FLUENT-calculations

Very fast activation of IN
<1ms

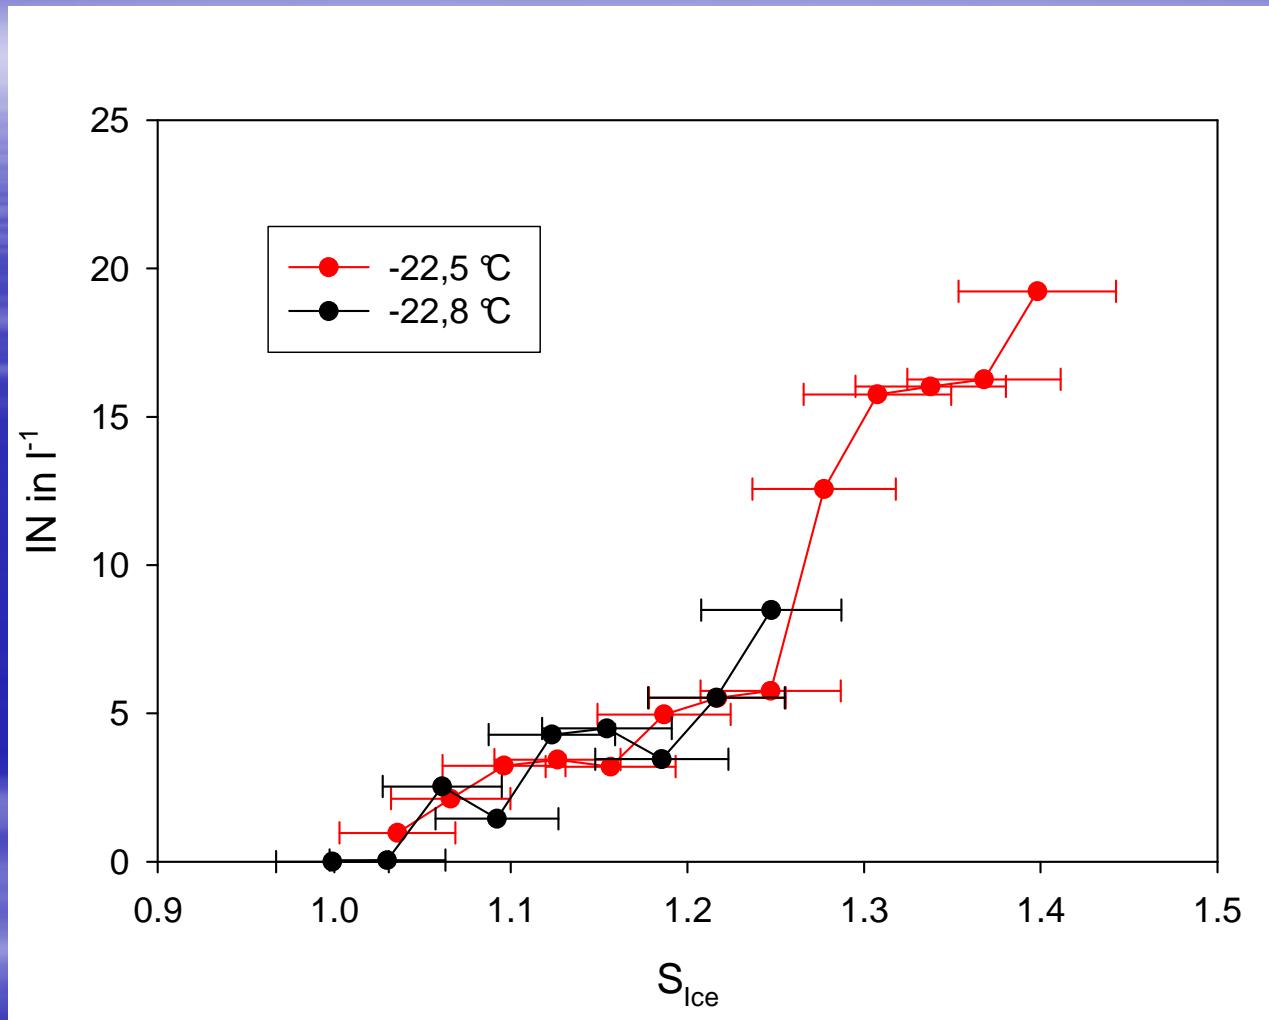

ATD

Start 18.9.
10:00 -10:20 AIDA
 $\text{CN}=280 \text{ cm}^{-3}$

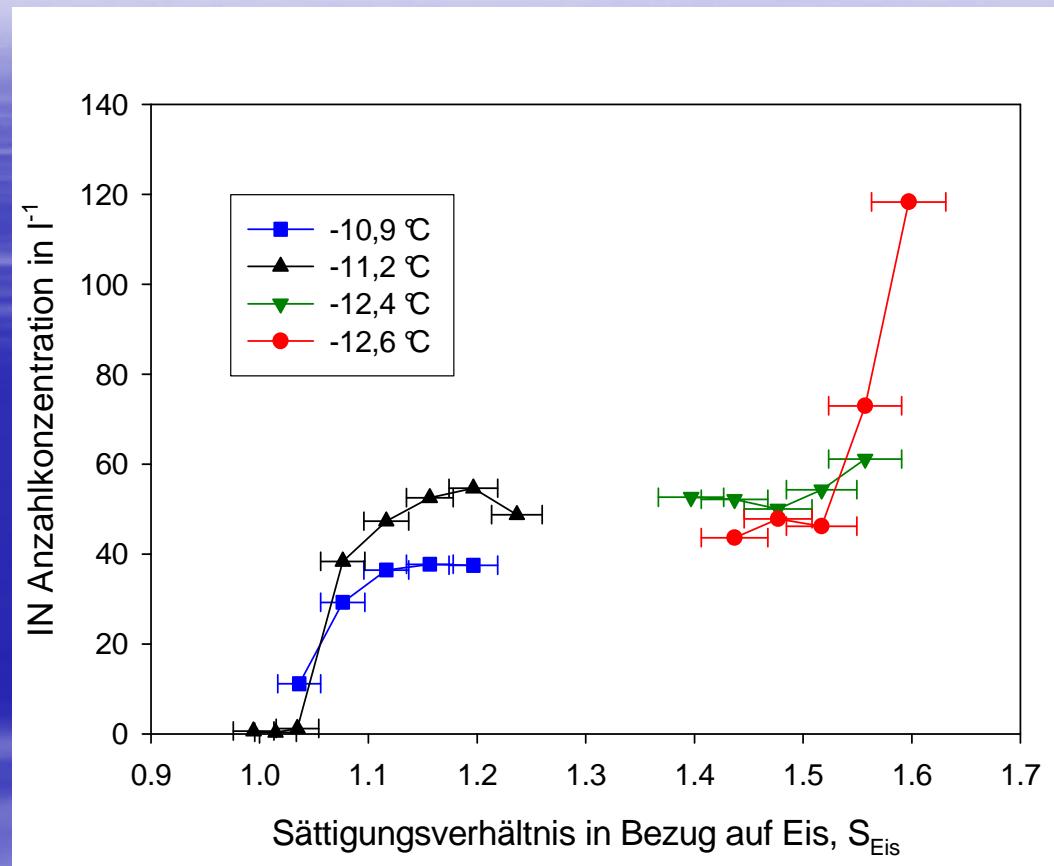

Start 18.9.
12:55 AIDA
 $\text{CN}=200 \text{ cm}^{-3}$

GfG soot

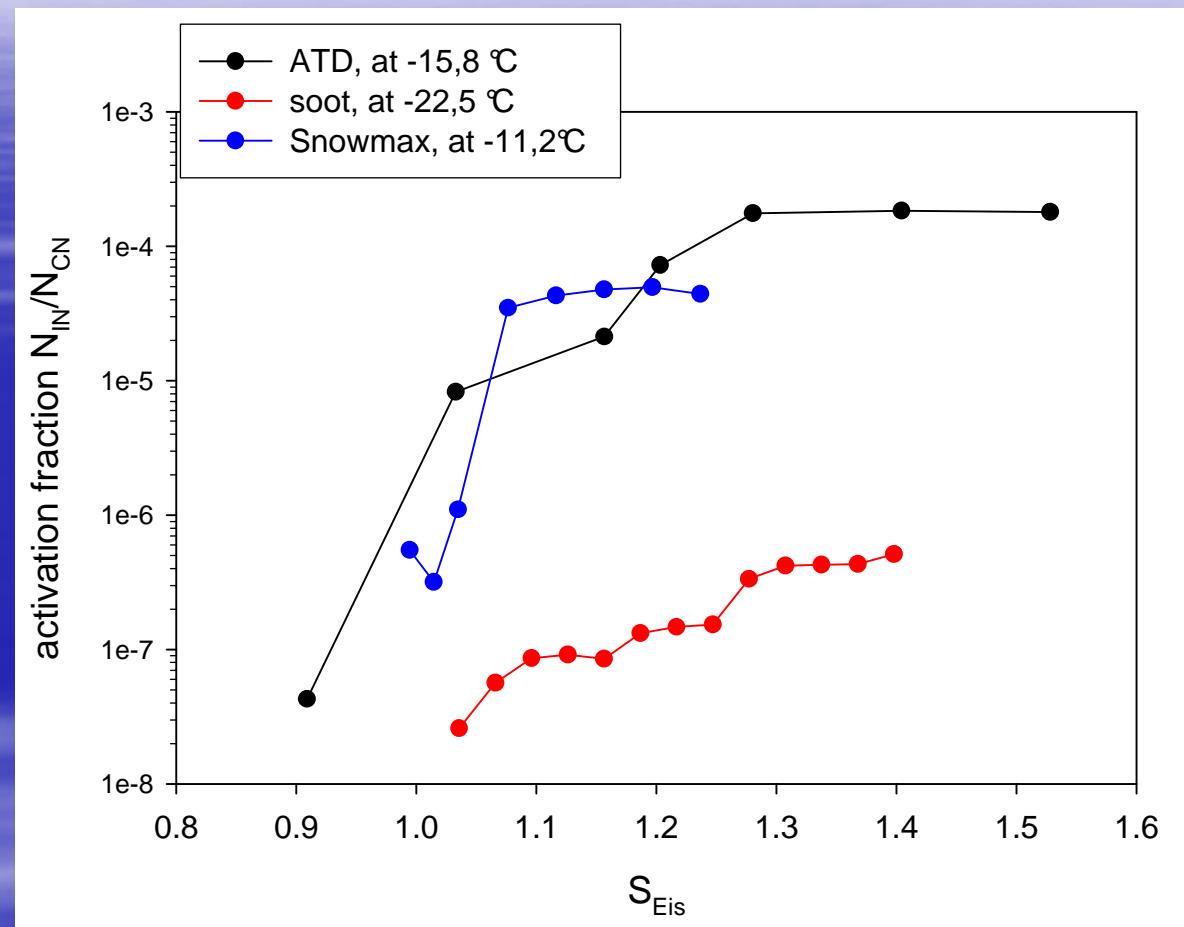

Start 20.9.
10:08 NAUA
 $\text{CN}=35000-40000 \text{ cm}^{-3}$

Snowmax

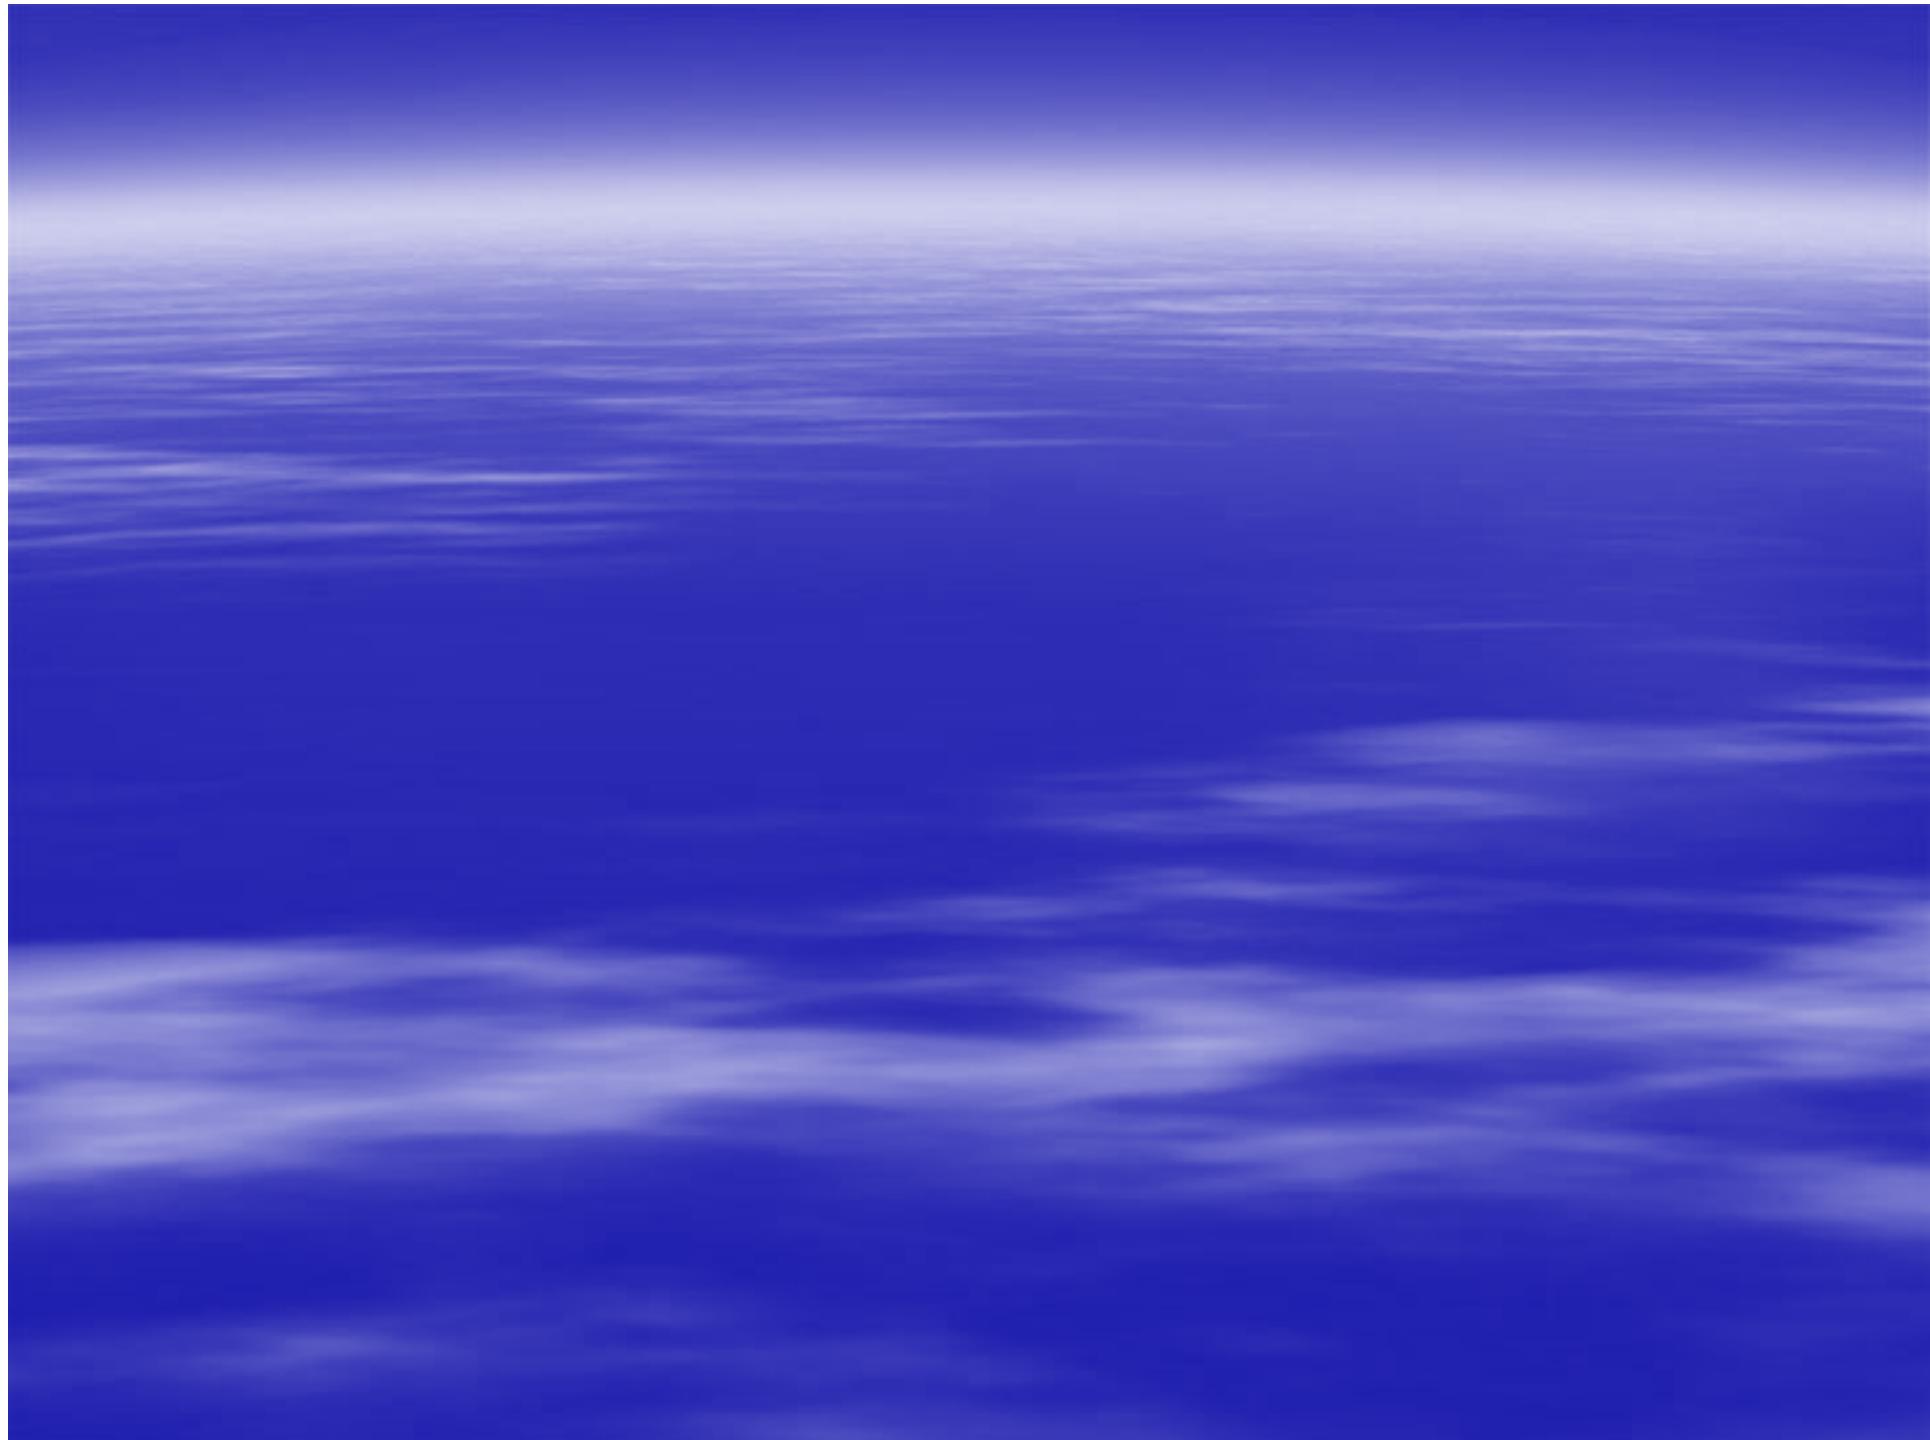

Start 26.9. 15:10
NAUA
 $\text{CN}=1100 \text{ cm}^{-3}$

Activation fraction N_{IN}/N_{CN}

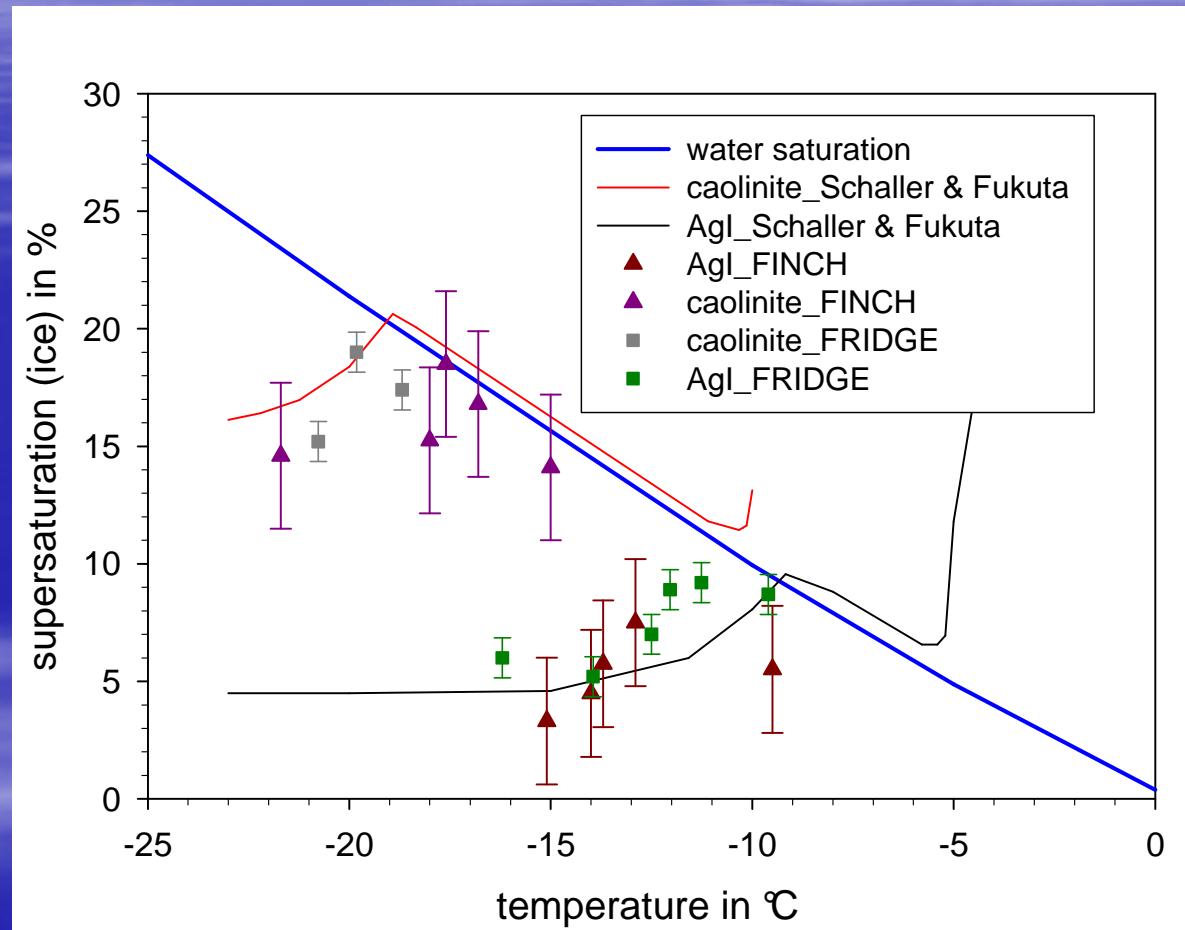

Conclusion

- Measurement of to low supersaturation (ICIS)
- Hint of very fast activation of the IN, <1ms
- Lower activation fraction in comparison with other IN-counter
- Limited IN number concentration (~300 IN/l)
- Low activation fraction of soot

Lab measurements
